Prompting

Prompting

Use the following text as the "content" in the Python program you tried last time to interact with the Qwen model, and then run the program:

```
text = """
The university library will close at 18:00 on Friday.
Students must return borrowed laptops before closing.
The study area will remain available until 20:00.
"""
```

Is the response from the model useful? Was the above text specific enough to tell the model what to do precisely?

Prompting

Now, add a prompt variable

```
prompt = f"""
Summarize the following announcement in one sentence.
{text}
"""
```

Run the program again, and see the change in Qwen model's output.

Prompting

Now, change the **prompt** to the following, and run the program:

```
prompt = f"""
Extract the closing time of the library from this announcement.
Return only the time.
{text}"""
```

Then change the **prompt** to the following and run it:

```
prompt = f"""
Determine whether students need to return borrowed laptops
before the library closes.
Return only YES or NO.
{text}"""
```

Prompting with system message

So far, you've been using only "**user**" role. Now, introduce the "**system**" role.

Update the messages variable to the following:

```
messages=[
    {
        "role": "system",
        "content": "You classify university enquiries."
    },
    {
        "role": "user",
        "content": prompt
    }
]
```

"**content**" for the "**system**" role specifies how the model should behave, and the "**content**" for the "**user**" role specifies what the model should process this time.

What you just did

- Here, you practice briefly some more ways of improving the prompt, and giving the model some more context with **`system`** role.
- This was just for practice.
- You don't have to submit anything.

That’s all for this practice
